## 1 Reinforcement Learning

Imagine an unknown game which has only two states  $\{A, B\}$  and in each state the agent has two actions to choose from:  $\{Up, Down\}$ . Suppose a game agent chooses actions according to some policy  $\pi$  and generates the following sequence of actions and rewards in the unknown game:

t	$s_t$	$a_t$	$s_{t+1}$	$r_t$
0	A	Down	В	-2
1	В	Down	В	-4
2	В	Up	В	0
3	В	Up	A	3
4	A	Up	A	1

Unless specified otherwise, assume a discount factor  $\gamma = 0.5$  and a learning rate  $\alpha = 0.5$ .

1. Recall the update function of Q-learning is:

$$Q\left(s_{t}, a_{t}\right) \leftarrow (1 - \alpha)Q\left(s_{t}, a_{t}\right) + \alpha \left(r_{t} + \gamma \max_{a'} Q\left(s_{t+1}, a'\right)\right)$$

Assume that all Q-values initialized as 0. What are the following Q-values learned by running Q-learning with the above experience sequence?

$$Q(A, Down) =$$
  $Q(B, Up) =$ 

2. In model-based reinforcement learning, we first estimate the transition function T(s, a, s') and the reward function R(s, a, s'). Fill in the following estimates of T and R, estimated from the experience above. Write "n/a" if not applicable or undefined.

$$\hat{T}(A, Up, A) = \underbrace{\hat{T}(A, Up, B)} = \underbrace{\hat{T}(B, Up, A)} = \underbrace{\hat{T}(B, Up, B)} = \underbrace{\hat{T}($$

3. To decouple this question from the previous one, assume we had a different experience and ended up with the following estimates of the transition and reward functions:

s	a	s'	$\hat{T}(s,a,s')$	$\hat{R}(s,a,s')$
A	Up	A	1	10
A	Down	Α	0.5	2
A	Down	В	0.5	2
В	Up	A	1	-5
В	Down	В	1	8

(a) Give the optimal policy  $\hat{\pi}^*(s)$  and  $\hat{V}^*s$  for the MDP with the transition function  $\hat{T}$  and the reward function  $\hat{R}$ .

Hint: for any  $x \in \mathbb{R}$ , |x| < 1, we have  $1 + x + x^2 + x^3 + x^4 + \cdots = 1/(1-x)$ 

$$\hat{\pi}^*(A) = \hat{\mathcal{T}} \quad \hat{\pi}^*(B) = \hat{\mathcal{T}} \quad \hat{V}^*(A) = \hat{\mathcal{T}} \quad \hat{V}^*(B) = \hat{\mathcal{T}}$$

- (b) If we repeatedly feed this new experience sequence through our Q-learning algorithm, what values will it converge to? Assume the learning rate  $\alpha_t$  is properly chosen so that convergence is guaranteed.
  - i. the value found above,  $\hat{V}^*$
  - ii. the optimal values,  $V^*$
  - iii. neither  $\hat{V}^*$  nor  $V^*$
  - iv. not enough information to determine

## 2 Policy Evaluation

In this question, you will be working in an MDP with states S, actions A, discount factor  $\gamma$ , transition function T, and reward function R.

We have some fixed policy  $\pi: S \to A$ , which returns an action  $a = \pi(s)$  for each state  $s \in S$ . We want to learn the Q function  $Q^{\pi}(s, a)$  for this policy: the expected discounted reward from taking action a in state s and then continuing to act according to  $\pi: Q^{\pi}(s, a) = \sum_{s'} T(s, a, s') \left[ R(s, a, s') + \gamma Q^{\pi}(s', \pi(s')) \right]$ . The policy  $\pi$  will not change while running any of the algorithms below.

- (a)  $Q^{\pi}(s, a) \leq Q^*(s, a)$  for all s, a
- (b)  $Q^{\pi}(s, a) = Q^{*}(s, a)$  for all s, a
- (c)  $Q^{\pi}(s, a) \geq Q^{*}(s, a)$  for all s, a
- (d) None of the above guaranteed
- 2. Suppose T and R are unknown. You will develop sample-based methods to estimate  $Q^{\pi}$ . You obtain a series of samples  $(s_1, a_1, r_1)$ ,  $(s_2, a_2, r_2)$ , ...  $(s_T, a_T, r_T)$  from acting according to this policy (where  $a_t = \pi(s_t)$ , for all t)
  - (a) Recall the update equation for the Temporal Difference algorithm, performed on each sample in sequence:

$$V\left(s_{t}\right) \leftarrow (1 - \alpha)V\left(s_{t}\right) + \alpha\left(r_{t} + \gamma V\left(s_{t+1}\right)\right)$$

which approximates the expected discounted reward  $V^{\pi}(s)$  for following policy  $\pi$  from each state s, for a learning rate  $\alpha$ . Fill in the blank below to create a similar update equation which will approximate  $Q^{\pi}$  using the samples. You can use any of the terms  $Q, s_t, s_{t+1}, a_t, a_{t+1}, r_t, r_{t+1}, \gamma, \alpha, \pi$  in you equation, as well as  $\sum$  and max with any index variables (i.e. you could write  $\max_a$  or  $\sum_a$  and then use a somewhere else), but no other terms.

where else), but no other terms.
$$Q(s_t, a_t) \leftarrow (1 - \alpha)Q(s_t, a_t) + \alpha[----]$$

(b) Now, we will approximate  $Q^{\pi}$  using a linear function:  $Q(s, a) = \sum_{i=1}^{d} w_i f_i(s, a)$  for weights  $w_1, \ldots, w_d$  and feature functions  $f_1(s, a), \ldots, f_d(s, a)$ .

To decouple this part from the previous part, use  $Q_{samp}$  for the value in the blank in part (a)(i.e.  $Q(s_t, a_t) \leftarrow (1 - \alpha)Q(s_t, a_t) + \alpha Q_{samp}$ ) Which of the following is the correct sample-based update for each  $w_i$ ?

i. 
$$w_i \leftarrow w_i + \alpha \left[ Q\left(s_t, a_t\right) - Q_{samp} \right]$$

ii. 
$$w_i \leftarrow w_i - \alpha \left[ Q\left(s_t, a_t\right) - Q_{samp} \right]$$

iii. 
$$w_i \leftarrow w_i + \alpha \left[ Q\left(s_t, a_t\right) - Q_{samp} \right] f_i\left(s_t, a_t\right)$$

iv. 
$$w_i \leftarrow w_i - \alpha \left[ Q\left(s_t, a_t\right) - Q_{samp} \right] f_i\left(s_t, a_t\right)$$

v. 
$$w_i \leftarrow w_i + \alpha \left[ Q\left(s_t, a_t\right) - Q_{samp} \right] w_i$$

vi. 
$$w_i \leftarrow w_i + \alpha \left[ Q\left(s_t, a_t\right) - Q_{samp} \right] w_i$$

- (c) The algorithms in the previous parts (part a and b) are:
  - i. model-based
  - ii. model-free
